Introduction

The Geodetic Coordinates Manual for the National Aeronautics and Space Administration Goddard Space Flight Center, Wallops Flight Facility includes the official list of geodetic coordinates for all facilities supporting assigned range projects.

In addition to a summary of definitions, the manual includes several sets of data. The first table lists the ellipsoid constants for each of the reference ellipsoids used in the manual. The second table contains the datum shift constants used in compiling the manual. Figure 1 is a map depicting each datum used. The number, location, name, and reference number for each station position found in the manual are provided in Table 3.0. Table 3.1 contains the same information as Table 3.0 but is sorted by position type.

The fourth table represents the original coordinate data for all station positions not originally provided referenced to the World Geodetic System 1984/North American Datum 1983. The position number, name, latitude, longitude, and mean sea level height are included in this table. The positions are grouped by location. Furthermore, the table is partitioned according to reference ellipsoid and datum. The first section, Table 4.0, contains data referenced to the Clarke 1866 Ellipsoid/North American Datum 1927. The next section, Table 4.1, contains data referenced to the World Geodetic System 1972 ellipsoid and datum. Data referenced to the International Ellipsoid/European Datum 1950 is presented in Table 4.2. Finally, Table 4.3 is comprised of data referenced to the International Ellipsoid/Qornoq Datum.

The World Geodetic System 1984/North American Datum 1983 ellipsoid and datum is the combination currently used for all data products generated in post flight data reduction. Coordinate data referenced to this ellipsoid and datum for all station positions is listed in Table 5. The number, name, latitude, longitude, and ellipsoid height for each station position is found in this table. The table is grouped according to location.

Mobile radars are frequently relocated. A history of their locations can be found in Table 6. The table is grouped by radar identification. Within each group the positions are listed in chronological order with the last known location listed last.

Finally, Table 7 is a comprehensive list of references indicating the source of the station position information found in this manual.

Definitions

Ellipsoid of Revolution

The ellipsoid of revolution is the geometrical figure used in geodesy to approximate the shape of the earth. It approximates the slight flattening at the earth's poles and bulge at the equator. The ellipsoid is generally defined with respect to its size and shape. Size is indicated by the radius at the equator, the semi-major axis. The degree of flattening, a measure of how closely the ellipsoid resembles a sphere, establishes the shape.

Geodetic Position

The ellipsoidal angular coordinates are geodetic latitude and longitude. The geodetic latitude is the angle described by the line normal to the reference ellipsoid at the point of interest and the plane of the equator. Latitudes are considered positive north of the equator and negative south of the equator. The geodetic longitude is the angle measured in the equatorial plane between the prime meridian (Greenwich, England) and the meridian of interest. In this document, longitudes are positive east of the prime meridian and those west of the meridian are negative.

Three reference surfaces are used in the determination of the vertical geodetic location of points: the physical surface of the earth, the geoid, and the geometric surface of the ellipsoid. Geodetic measurements are made on the physical surface of the earth to establish the heights above mean sea level of vertical control points. The geoid is defined as the equipotential surface in the gravity field of the earth which coincides with the undisturbed mean sea level extended continuously through the continents. Since the distribution of the earth's mass is uneven, the geoidal surface will be somewhat irregular; thus, the areas of separation between the geoid and the regular ellipsoid are referred to as the geoid heights or geoid-ellipsoid separations. The geodetic height is the computed height of a point above or below the geometric surface of the reference ellipsoid. This value is approximated by adding the height above mean sea level and the geoid-ellipsoid separation.

Geocentric Position

The geocentric positions are defined in a spherical Cartesian system with the origin at the center of the reference ellipsoid. The X, Y and Z coordinates are defined as follows: X lies on the intersection of the prime meridian and the plane of the equator, Y lies 90 degrees east of the prime meridian and Z is coincident with the earth's axis of rotation. Although geocentric coordinates are not included within this manual, the geocentric latitude and geocentric radius of the earth for the site positions are included in the coordinates file.

Geodetic Datum

The geodetic datum is a surface referenced to an ellipsoid used for positioning points on the earth's surface. Figure 1 illustrates the location of each geodetic datum referred to within this manual.

Geodetic Datum Shifts

A geodetic datum is associated with a particular reference ellipsoid; therefore, it may be necessary to shift the datum (U, V, and W shifts) in order to transform a site position to the new reference ellipsoid.

Table 1 - Reference Ellipsoid Constants

Reference Ellipsoid	Semi-Major Axis (meters)	Inverse of Flattening
Clarke 1866	6,378,206.4	294.9787
Clarke 1880	6,378,249.145	293.465
International	6,378,388.0	297.0
World Geodetic System 1972	6,378,135.0	298.26
World Geodetic System 1984	6,378,137.0	298.257223563
